Academic Study with Banner Gap 30pt

Abstract

This study investigates multi-column segmentation under varying vertical separation intervals. We systematically evaluate whether recursive projection profile analysis cleanly isolates spanning banners from underlying columnar blocks.

1. Left Column Analysis

The primary hypothesis asserts that banner boundaries must be established before column gutter analysis is performed.

Failing to separate banners causes spanning lines to block column detection.

2. Right Column Results

Experimental findings confirm that adaptive band grouping completely resolves line interleaving.

Sequential reading order is preserved across all tested separation intervals.
