Scalable Layout Analysis for Mobile Devices

An Empirical Investigation into Deterministic Reconstruction

1. Introduction

Document reconstruction on mobile devices requires robust spatial partitioning. When reading a two-column layout, content must proceed down the entire left column before transitioning to the right column.

2. Left Column Details

Without proper bounding box geometry, naïve parsers interleave horizontal rows between adjacent columns, resulting in scrambled sentences and unreadable output.

3. Right Column Progress

The right column continues the primary narrative thread. Spatial XY-cut algorithms project horizontal and vertical white-space gutters across the page to isolate column blocks cleanly.

4. Conclusion

Evaluating spatial separation ensures that column order is preserved under all zoom levels and font resolutions.
